

Platform Architecture and Interface Documentation

Name	Jannani R
Roll Number	241401031
Department	Computer Science and Business Systems (CSBS)
Year/Semester	III year / V Semester
Course	Low-Code Application Development using Zoho Creator

This document provides a concise overview of the Zoho Creator platform architecture and its user interface components, covering the purpose and core functionality of each major module. It is intended to help users understand how the platform's features work together to support low-code application development, workflow automation, data management, and business process optimization.

Feature Name: Applications

The Applications module is the central workspace where users create, access, and manage all low-code applications. The dashboard displays application cards with quick actions such as Edit, Open, and More Options, along with a Create Application button, search bar, and filters. It centralizes multiple business apps — such as Employee Management, CRM, and Inventory systems — in one place, simplifying navigation and improving productivity.

Feature Name: Microservices

Microservices lets users build lightweight, independent service components that integrate with third-party applications, expose APIs, and run custom automation without affecting the core application. Because each service is modular and reusable, teams can update or scale integrations — such as payment processing or customer notifications — independently, improving flexibility and reducing deployment risk.

Feature Name: Environments

Environments provides a multi-stage deployment framework with Stage and Production spaces, allowing new features and fixes to be tested before going live. Options such as Add Application, Version History, Manage, and Publish let teams track versions and control releases, minimizing risk and ensuring stable, error-free updates to production applications.

Feature Name: Mobile

The Mobile module converts Zoho Creator applications into Android and iOS apps. Users can access apps through the Zoho Creator mobile app, or with a paid upgrade, publish a fully branded app on the Play Store or App Store, distribute it via MDM, or share installation links directly — extending secure, branded mobile access to employees and customers.

Feature Name: Portal

Portal creates secure, self-service gateways for external users — customers, vendors, or partners — to interact with applications without accessing the core workspace. Administrators configure role-based access to expose only relevant features and data, supporting use cases such as student portals or vendor and customer service portals, while maintaining data privacy.

Feature Name: Users

The Users module manages everyone with access to applications using role-based access control (RBAC), assigning appropriate permissions from Super Admin down to limited roles. Administrators can add, search, and filter users, and view details like email, role, and status, ensuring only authorized users can reach sensitive applications and data.

Feature Name: Organization

Organization centralizes company profile, branding, and system preferences — logo, favicon, contact details, namespace, and time zone — so every application reflects a consistent identity and operates under the correct regional settings. This keeps branding and administrative details standardized across all applications in the organization.

Feature Name: Governance

Governance lets administrators define security policies, authentication rules, and access controls organization-wide, including password policies, multi-factor authentication, Active Directory integration, custom authentication, and trusted domains. It strengthens security and helps organizations, such as financial firms, meet compliance requirements for controlled application access.

Feature Name: Metrics

Metrics monitors and analyses user activity across applications, surfacing usage trends, engagement patterns, and anomalies once enabled, subject to required data-processing consent. It helps administrators identify frequently used or inactive modules, detect unusual login activity, and make data-driven decisions to improve application performance and user experience.

Feature Name: Operations

Operations is a centralized hub for administrative functions, including Backup, Audit Trail, Email Management, API Management, Logs, Publish, Marketplace, System Integrations, Zia, Payment Gateways, and Databridge. It lets administrators manage backups, integrations, and publishing from a single dashboard, simplifying maintenance while improving governance and operational efficiency.

Feature Name: Billing

Billing gives administrators visibility into subscription plans, trial status, and resource usage, including users and applications consumed against plan limits. A Usage Details dashboard tracks consumption with custom alerts, helping organizations proactively monitor limits and upgrade plans as user and application needs grow.

Conclusion

Zoho Creator offers a complete low-code ecosystem that supports every stage of application development, from building and testing to deployment, security, and monitoring. Modules such as Applications and Microservices enable rapid creation of business solutions, while Environments and Operations ensure safe, well-governed deployment. Mobile and Portal extend application access to employees, customers, and partners across devices and platforms, and Users, Organization, and Governance work together to keep access secure, branded, and compliant with organizational policies. Metrics and Billing further support informed decision-making by giving administrators visibility into usage patterns and resource consumption.
